Oliver

I am looking through the paper file, which only covers 2007- early 2009. There are no limits set on the basis of IC4 by that time, which is unsurprising.

Testing showed values around 1mg/m³ particulates and the emission points are dust filters. My opinion would have been that such emission points (package dust filters on extraction duty)- shown as they were to be well managed- would not justify further interest in terms of ELVs. Control would be via appropriate preventative maintenance of filter media under the EMS. Which would be why I didn't set any limits at the next variation.

Regards
