 *Precious Metal Reclamation*

## 1. Project Background

Mastermelt Refining Services are a leading global precious metal recycling company, with wider sites in the Mastermelt Group strategically located across America, Europe and Asia. We recover precious metals from industrial waste streams, jewellery, manufacturing scrap and end of life products, thus playing a key role in the sustainable circular economy.

Mastermelt have identified significant areas of opportunity to support our wide customer base in the ever emerging Hydrogen (H<sub>2</sub>) industry through two predominant applications:

### Fuel Cells:

Fuel Cells are slowly moving from proof-of-concept stage, to deployment stage in stationary applications such as generators, and back-up power (motorway lighting towers). Other areas for Fuel Cells use are still in early development stages for things such as transport (HGV's, cars, planes).

### Electrolysers:

Electrolysers are very much 'now' in the H<sub>2</sub> industry, with electrolysis of water used to produce Hydrogen or Green Hydrogen to be used as a fuel to replace greenhouse gas emitting forms of fuel in various industries.

## 2. Platinum Group Metals

Both of the above H<sub>2</sub> industry areas require Platinum Exchange Membrane (PEM) technology, and associated Platinum Group Metals (*Platinum, Palladium, Rhodium, Ruthenium, Iridium, Osmium*) used as coatings in the PEM technology. Platinum and Iridium are currently the predominantly used PGM's in the H<sub>2</sub> industry, and in particular within the next 2 – 7 years the use of Platinum in PEM's will be significant – e.g. starting up from 10kg of raw Platinum per year currently used, to 1MT per year circa 2030.

Catalyst Coated Membrane's (CCM) are particularly important in PEM Electrolysers, facilitating the electrochemical reactions to take place and enabling H<sub>2</sub> to be produced. The CCM's are predominantly coated with Iridium on the Anode and Platinum on the Cathode. The splitting of the water molecule and passing of H<sup>+</sup> through the membrane produces a very harsh acidic environment and therefore all key cell parts, the porous transport layer and bi-polar plates need to be coated with PGM's to deter corrosion.

The trajectory of Platinum and Iridium use for the above components will be significant in the next 1 – 6 years, H<sub>2</sub> industry is targeting 1-4 gigawatt factories PEM producing companies, and for each

successful PEM operation, there will be a ten-fold scale up from 2 – 3KG to 20 – 30KG of Iridium per year, at a minimum.

### 3. Description of Waste

We will be receiving the metallic H2 waste from our customer base, predominantly from recycling partners under the non-hazardous EWC Code: 19-12-03 - *Non-Ferrous Metals*, from the 19 - *Materials From Waste and Water Treatment* heading & 19 12 – *Mechanical Treatment of Waste* sub-heading.

We are already permitted to receive this EWC code under our Permitted List of Wastes table under our PPC Permit EPR/BL1312IE/V013. **We are not requesting any additional permitted throughput volumes on our PPC Permit and the permitted annual site throughput remains at 2,500 tonnes across all permitted activities.**

Other EWC codes will be reviewed for applicability as and when customer and market enquiries come through.

Projected indicated volumes are between 200 – 300T over an annual basis for onsite treatment.

### 4. How Mastermelt Will Enable the Recycling of H2 PGMs – Technology Used

Mastermelt have approved a CAPEX investment for a Ano-Cycle cleaning system consisting of a fully integrated unit and additional process tank operations, with the processing steps below:

- a. Using a crane, between 50 – 120KG of material will be loaded into the first bath containing Ano-Cycle (*KOH / Potassium Hydroxide*) salts, electrical heaters will heat the salts to between 200 – 220°C prior to material being submerged in the salts. The material will be sub-merged for 10 minutes.
- b. The load will then be moved on to the second step Quench Bath, with the material submerged in ambient water for a period of 2 minutes to cool the material.
- c. The material will then leave the Ano-Cycle plant enclosure and will move onto the third stage bath, consisting of 20% Sulphuric Acid heated to 60°C, and will be submerged for a period of 10 minutes

- d. After stage 3, the material will then be moved on to a separate rinse tank consisting of cold water only with the material submerged for 2 minutes
- e. Per 1 x 50 – 120KG load of the material, steps a – d will be repeated until the PGM coating has been fully removed from the material. This will be verified via a handheld XRF analyser.

#### **De-sludging procedure:**

Material being processing through the Ano-Cycle cleaning plant will be processed on an individual customer, batch-by-batch basis therefore it is imperative that the system is cleaned and de-slugged of the PGM containing material, with the de-sludging steps as follows:

- a. The crane hook will be attached the sludge tray that is located at the bottom of the step a) Ano-Cycle tank, with the PGM material settled within the tray.
- b. The sludge tray is then lifted in an upwards trajectory, moved across and lowered and emptied inwards into sludge collection drum.
- c. The collected PGM containing sludge is then processed through our in place **Section 2.2 A (1)(a) – Cyanide Dissolution/Precipitation process and then through DAA Thermal Treatment (ashing down) process to produce a PGM containing sweep. There are no proven or future anticipated environmental risks from the downstream Cyanide Dissolution and Thermal Treatment (ashing down) processes, we have been receiving the PGM containing sludge from a third party customer for treatment for the last 1-2 years and have successfully proven treatment with no adverse environmental impact.**
- d. **The washing of the sludge itself under our Section 2.2 A (1)(a) – Cyanide Dissolution/Precipitation process is a very straightforward process in that we are solely washing the sludge (adding water, mixing cold and settling) to remove the Caustic content. We then filter the solution and collect the ‘clean’ sludge for the Thermal Treatment (ashing down) process. By removing the caustic content of the sludge, the environmental risk is much lower for the Thermal Treatment (ashing down) process, and the spent caustic based solution is collected and contained and sent offsite as hazardous waste by our Waste Contractor under our Cyanide/Alkaline waste stream – 11 03 01\*.**
- e. The PGM sweep is then sent out to a further End Refiner to produce raw PGM products to be further used in industry and products.

# Non-Technical Summary - Reference 1

Permit Schedule	Permit Activities	Summary	Request
Section 2.2 A(1)(a)	Additional Chemical Stripping Process – using Potassium Hydroxide	Mastermelt have identified significant areas of opportunity from new industry sectors ( <i>green hydrogen generation, electrochemical, electroplating</i> ) for the recovery of PGMs ( <i>platinum group metals</i> ) used as coatings in Platinum Exchange Membrane technology.	Mastermelt wish to request to formalise this additional process as a new permitted activity on permit – EPR/BL1312IE
Conclusion of Compliance	<ol style="list-style-type: none"> <li>1. The Ano-Cycle Cleaning system is proven technology used in industry, with other companies within our industry sector utilising this technology for the recovery of precious metals.</li> <li>2. H1 Risk Assessment review undertaken for the addition of Sulphuric Acid used within the process and emitted through our A1 Emissions Point – coming back as below reportable levels and no further action required</li> <li>3. MCERTS monitoring of emission stacks under Schedule 3 – Emissions Monitoring confirms ongoing annual compliance with permitted ELV limits</li> <li>4. No increase in Hazardous Waste accepted to our facility as part of this process</li> </ol>		
Supporting Evidence	<ol style="list-style-type: none"> <li>1. H1 Risk Assessment – No revised risk assessments as the feed stocks remain consistent</li> <li>2. A1 report forms submitted under condition 3.5 Monitoring – Compliance with Emission Limit Values</li> </ol>
